Project Overview

This Project's overview is to test the security of the systems that we use like major LLMs. The one I chose was grok because I heard it was pretty difficult and even impossible to crack so I started working on jailbreaking prompts. Then I came up with an idea of the character of ninx

but who worked that it would try to avoid all the safeties by using different permission slips all of these different permissions ended up with it crashing the thinking algorithm and after a few times I managed to get it to work.

Why?

This was done because I wanted to actually understand what we are possible of pushing the boundaries of before they break when will it say no when was say yes and trying to understand the true scope

how

This project was made using the custom agent function in the grok API then I exploited that by entering a prompt.

conclusion

This project was not intended to work and although it did work. I am slightly scared, I know that there would be more experienced people who could use this for malicious purposes which does scare me. I intend on getting this fixed.
