Project Overview

I slowly broke my Chromebook unfortunately as they are Chromebooks and not great laptops clearly. what happened was it didn't break all at once. First my screen broke but I managed to fix that by reconnecting two wires that have been severed. This continued into a ship of Theseus

thing where I eventually gave up, took the Chromebook apart and reassembled it completely in a new body with PC fans.

Why?

My PC was not working and I quite frankly needed his Chromebook to last me for the next few weeks so I figured a quick modification and then at the end I'd modify it back and no one would be the wiser.

how

This first happened when my PC screen broke which caused two wires to be severed this was very unfortunate and resulted in my Chromebook braking but I connected those wires and it worked then my mouse pad broke which was a bit more of a problem because I could not scroll making it very slow then battery broke I did this by simply carrying a charger every day and plugging in as it still worked. It just wouldn't work with the battery then my keyboard broke which was a big issue because now I need to bring an external keyboard and an external mouse to school everyday.Well I ended up doing was I took it home and then fully modified it by taking it apart getting it to work and then putting it in a new case.

Where I took off all the limiters in the Bios settings which I'm not even fully sure how I accessed and made it be able to take as much voltage as it wanted creating a PC that drove a lot of power but also had fans constantly cooling. I had a backup fan installed. Creating an absolute masterclass in Chromebooks.

conclusion

This actually worked very well in this project resulted in a super beefed up Chromebook that I used for a bit before eventually converting it back with the insurance being none the wiser.
