Project Overview

This was my first in basic rocketry design via the use of propellants this originally started out as a Boy Scout project but then I came back to it later recruiting much more successful bottle rockets utilizing water but also materials to avoid the viscosity of water making it even stronger

and faster than I found the best altitudes to launch at and the best amount of water. The weather had a big effect depending on humidity.

Why?

This was done because I truly wanted to get more experience firing things to the sky safely. This will be seen later in the potassium nitrate I am working on and that report will be out soon.

how

This was done using a bottle of bike pump and specially caught in quarks I set up a basic rail to have a basic landing pad and then add a different

things I found out with a landing pad you could push it hard there due to displacement laws

conclusion

This was a really fun project and I would like to do this again as I learned a lot about propellants how this work depends looking to NASA's official guide for this stuff it's very interesting.
