Project Overview

I created DIY grow lights in order to grow different crops such as basil cilantro and Thyme project was a success

Why?

Grow lights were expensive and would take a while to get to my location so I figured it would be easier just to repurpose old LED strips into grow lights of my own I would like to make these growing enclosures into a more formal thing now we'll be doing another portfolio on them

how

Was done by soldering together RGB strips and adjusting the color frequencies as so created special ratios of light to mimic sunlight that could grow plants

conclusion

The experiment worked and the plants grew. It was a very good experiment in general and I believe my next project would be to make this more widespread. Success
