Project Overview

So now I made basic Environment using soil the RGB grow lights mentioned in a previous project humidity temperature and moisture detectors And a basic car battery powering the whole setup making it so I can finally enjoy basil at lunch time

Why?

My food is very Bland so as a workaround too bringing lunch from home I figured if I have basil growing there I can get fresh lunch every day and enjoy my sandwiches

how

I decided that if I wanted to do this I need to have a basic plant growing chamber in my locker this would be challenging but would be worth it started this creating a basic anti rotting system at the bottom using scraps of 3D printer filament after that I took soil and started planting seeds once I did that the next thing I did was create a basic humidity temperature and moisture sensor via Arduino and then I did the grow lights I made soon I was raising my plants in my house school

Conclusion

This project went very well unfortunately this resulted in my locker being raided by the principal due to the light coming from it.

unfortunately the school realized the glowing Hue coming from my locker and had someone sent in to take down my lock and shut it down when this happened they were more confused I thought I was growing weed but that is okay and it all turned out all right
