Project Overview

This bot was created to try uneven ground because instead of wheels it would have a sort of legs that would work in a pusher mechanism. This entrance had not been tried before tried by me and I had a very good time working on this one.

Why?

I wanted to try different high efficiency ways of moving payloads such as these legs that could go on uneven trying and even go on inclines and declines which is one thing Wheels would struggle with especially at Low torque.

how

This was done using two motors in a basic step system that would increase their torque while lowering their speed making it possible for the legs to move other than that I created better leg mechanisms for efficiency. then I added a 3.3 volt

battery and a TP 0568 charger module

conclusion

This was a lot of fun and was my first Approach at creating good charging modulesAnd batteries that would not be replaced other than that most of the project is pretty standard using laser cutting and different methods.
