Project Overview

The goal of this project was to build a potato cannon that could fire basic projectiles. This was done via using an aerosol to have a basic combustion mechanism similar to the ones used during world war 1 for artillery; this was using a transformer to generate a spark and high voltage.

Why?

This was one of the first projects that I have wanted to do ever since I got the *backyard ballistics* book. I have always loved the concept of propulsion and projectiles. So this project was very exciting.

how

This was done via a transformer mechanism being used with a 9 v battery. With a basic switch to turn it off and on making a basic arc. Igniting the spray causes it to expand and propel the payload out of the barrel.

conclusion

This was a very fun and good project that taught me a lot about explosions and safety. I made sure to always have safety goggles and a shield while testing (also had gloves just in case). This was to ensure safety and all around good practices. This project is a success and I will continue to optimize it.
