Project Overview

This bot was made to be a pathfinding but this would work by having two triggers in the front of the trigger goes it reversed the polarity on one of the wheels this basic setup would make it so if it hits an object it will automatically turn away from it although pretty simple this could be very

useful for creating something similar to a Roomba later.

Why?

Moving in the future I'd like to make more remote-controlled things and it would be a lot easier if when it hits a wall it'll automatically re-orient itself. This especially with the teleopathology I am aware of could be very useful.

how

This was done using a basic wood cut out and then two wooden antennae then they were set up to trigger buttons and the basic Wheels we have used

in previous projects after that I laser cut a top shelf to make it look like a Pokemon of sorts

conclusion

This was a very successful project and I created a basic pathfinding bot that would never crash into walls and be stuck instead when it crashed it would simply reorient itself and continue going would like to do more research in this later
