Project Overview

The project was done to experiment with piezoelectric discs and how they can be used to generate power and how that power can be used to do other things. These other things we're going to be charging my phone with other devices as it would serve as a basic power bank charging up an 18650 battery.

Why?

This was done to test transistors and different parts such as piezoelectric discs on top of that. done to work on 3D prints andAnd try cutting different things and soldering better.

how

This was done using first a basic tinkercad design then taking something and turning it into a fully working piezoelectricity powered disc although took time to get there it worked very well and I needed different resistors and transistors but it all came

together to work and charge up the battery pretty successfully in charge of my phone.

conclusion

I would like to try and optimize this design as although it worked it did not work amazing and I think I could probably adjust it to make it better. This was a lot of fun and I should definitely try it again now that I have a better knowledge of electricity components and perf boards
