Project Overview

In this project I created a working electrolysis machine turning water into hydrogen basic oxy hydrogen reactor. I could later use it to explode this gas for other projects and things such as the Iron Man initiative.

Why?

I wanted a chemistry project and I wanted to have access to a lighter than air chemical explosive with a high yield.

how

This was done via a few basic variations starting off with a very simple version starting with screws to a more complex version of steel rods, basic connectors a managing thing and optimized connection points. In these versions were documented in a video I'm currently working on and will be uploaded next to this hopefully.

conclusion

This project went out with a bang and created exactly what I was hoping for. Oxy hydrogen in solid quantities that provided rather safe but a solid amount to use for any experiment. It was a really great example of how different chemistry and how Innovation can cause a project that I struggled with for years to finally work.
