Project Overview

This project was part of a school project for robotics too. I needed to prove that I had experience and understanding in both cataloging my research. (now that I realize that I am doing that right now and actually building prototypes and evolving a project) this took a quarter of the year and was a lot of fun and a very good time.

Why?

This was done because I need to do my school's intermediate robotics program to move on to the advanced one. I would really like to do the advancement because this combines electrical engineering with mechanical and coding as that is the trisect that we call robotics.

how

This was done in my school's workshop with machine aluminum parts and an Arduino Uno on top of those actual components. What we did for this project was create a remote control car that had an arm on the front and would not crash into things via ultrasonic sensor.

Conclusion

This was a very fun project and although we did not fully get a successful final design we still managed to get all A's as our documentation and our science and engineering was heavily on par.
