Debrief after first test

The goal of this project is to make a Thrust vector control unit for model rocketry but in order to do that I require the skills to actually build my own Rockets. In order to do that I managed to get my hands on some rocket fuel and started 3D modeling different rocket ideas. I'm currently

figuring out the composition as my rocket fuel is given to me by a chemistry teacher. I get to work with and he and I are currently reconvening soon in order to make it better.

The first rocket take off wasn't actually a takeoff, it was more of a few burn tests. Today was the first takeoff because I built a rocket shell for it and even though it was facing the ground we did go to successful fire off in order to improve.

Next steps

I realized that lighting the fuel on fire took a ridiculously long amount of time for an ignition so I will need to work on making a fuse or finding it the next step will be doing the inverse chemistry in order to make an effective fuse.
