Project Overview

The goal of this project was to create a keyboard emulator. Via a pro microboard this board would serve a US keyboard making the computer trick superhuman inputs inserted as a rubber ducky just to look like humans. This control means you can practically take control of some

computer and try to tell me some way.

Why?

This was made to see if you can create control over the computer. With a basic \$5 check and what could be done with this potential search for the keyboard shortcuts and power washing. this could be seen in our later initiatives.

how

this will be done with the pro microboard flashing an Arduino IDE software creating basic code then it will be used to emulate a keyboard and insert keyboard commands at super human speed

conclusion

This project worked amazingly and I could successfully open no bad type closed notepads and even something I didn't expect to take control of mice. We'll have to continue my research. This will be seen later in the fake AI project and lock down breaker project.
