## Project Overview

This project was building a turret in order to gain extra credit in robotics and Understand how stepper Motors worked a bit better. and the true capabilities of a uln 203 stepper motor of a prototype Shield. I wouldn't need a external power supply for this which I jerry-rigged

### Why?

This was done for my robotics project for extra credit and testing the different capabilities of a 3D printer. Microcontroller and jerry-rigged power supply such as AA batteries in series.

### how

This was done for my basic prototype via tinkercad as that is the only software I knew back then. Then setting up some basic wiring up and extracting the inner workings of a gel Blaster from a toy.

### conclusion

This project went very well and demonstrated that joystick libraries worked very well and the uln 203 server Motors. I bought them well and the power bank a jerry-rigged worked at at least somewhat efficiently to work.
